## Abstract

Particulate matter significantly reduces life expectancy in India. We use a randomized controlled trial in the Indian state of Punjab to evaluate the effectiveness of conditional cash transfers (also known as payments for ecosystem services, or PES) in reducing crop residue burning, which is a major contributor to the region's poor air quality. Credit constraints and distrust may make farmers less likely to comply with standard PES contracts, which only pay the participant after verification of compliance. We randomize paying a portion of the money upfront and unconditionally. Despite receiving a lower reward for compliance, farmers offered partial upfront payment are 8-12 percentage points more likely to comply than are farmers offered the standard contract. Burning measures derived from satellite imagery indicate that PES with upfront payments significantly reduced burning, while standard PES payments were inframarginal. We also show that PES with an upfront component is a cost-effective way to improve India's air quality.

# 1 Introduction

Worldwide, poor air quality is a leading preventable cause of death and morbidity (Fuller et al., 2022). Air pollution reduces the life expectancy of North India’s roughly half a billion residents by up to seven years, which represents one of the largest health burdens from pollution in the world (Lee and Greenstone, 2021). The use of fires to clear agricultural land in India, as in other low- and middle-income countries, is a major source of this pollution. Despite a clear economic case for reducing this pollution, as well as efforts to prohibit and fine those who produce it, agricultural pollution in North India has increased over the last few decades (Appendix Figure A.1). Arguably, existing policies have failed to account for incentives of two groups of actors: local officials’ incentives to enforce penalties when the costs and benefits of polluting activities are in different political jurisdictions, and farmers’ incentives to protect the environment given that the costs of pollution are largely borne by others.<sup>1</sup> In this paper, we ask whether a policy that explicitly considers these incentives can reduce pollution.

Every winter, farmers in North India burn rice stalk (residue) to clear fields. Smoke blankets the region and spreads downwind to major population centers such as New Delhi, affecting the health of millions of people (Cusworth et al., 2018).<sup>2</sup> According to the Global Burden of Disease, crop residue burning caused 66,000 premature deaths in India in 2015 (Global Burden of Disease Working Group, 2018). A back of the envelope calculation suggests around 8.7 million acres of annual burning across North India.<sup>3</sup> Using these estimates and focusing on the mortality cost alone, valued at a statistical life value of \$1 million, the average annual external damages per acre are \$7,600.<sup>4</sup> In comparison, paddy production generates

---

<sup>1</sup>Dipoppa and Gulzar (2022) provide evidence of this inter-jurisdictional externality, which undermines state and local actors’ incentives to enforce fines and bans. Farmers’ political clout and equity concerns around penalizing small farmers undermine enforcement even further.

<sup>2</sup>Beyond India, pollution from crop residue burning contributes to the pollution burden in China (Chen et al., 2017), Southeast Asia (Oanh et al., 2018), and Africa (Cassou, 2018).

<sup>3</sup>Our estimate is based on paddy burning estimates from Liu et al. (2020), who estimate a burn rate of 50% for all paddy acreage in Punjab, Haryana and Uttar Pradesh.

<sup>4</sup>Climate change, labor productivity, and morbidity costs aren’t included. Murali et al. (2010) estimates that residue burning in India emits around 4 million metric tons of carbon dioxide equivalents each year, or one percent of annual global greenhouse gas emissions (NASA, 2017; Jain et al., 2014; Sarkar et al., 2018; Shindell et al., 2012).

about \$500 per acre in revenue; profits are, of course, even lower.<sup>5</sup> For consumer welfare to outweigh the mortality costs of burning, average willingness-to-pay for rice would have to exceed 15 times the market price. This implies that eliminating the practice would almost certainly increase societal welfare.

Since 2015, farmers in North India face bans on burning residue, and the government subsidizes machines to remove and manage it. These policies, however, have been ineffective. In this paper, we investigate the feasibility of Payments for Ecosystem Services (PES) contracts, which pay farmers for not burning crop residue. PES programs raise the private cost of environmental degradation by conditioning cash transfers on avoiding an environmentally harmful behavior. By using a carrot rather than a stick, PES avoids the political challenges of fines. By placing the incentive on the desired outcome rather than the input, PES is a more flexible approach than equipment (input) subsidies.

However, contextual and institutional factors may limit the efficacy of PES — and, more broadly, conditional cash transfers — in low- and middle-income countries. PES participants must undertake a costly action to comply with the program and receive payment. Farmers may not comply if they do not trust that the conditional payment will be made, or if they lack the cash on hand to pay for alternatives to burning before receiving the PES payment, limiting PES efficacy.

PES contracts that offer partial payment in advance may help with trust and liquidity. An upfront payment can send a costly signal, increasing trust that the subsequent conditional payment will occur. It can also alleviate liquidity constraints when farmers need to spend money on alternatives to burning. However, recouping the upfront payment if the participant fails to comply is frequently infeasible or undesirable in low-income settings. Practically, upfront payments must then be unconditional, potentially undermining their usefulness for at least two reasons. First, for a given total payment, offering some of it upfront and unconditionally lowers farmers' marginal incentive to comply because the conditional payment is smaller. Second, given a certain level of effectiveness, upfront payments

---

<sup>5</sup>District-level data from ICRISAT show that in 2017, rice yields in Punjab were on average 17 quintals per acre, with a maximum yield of 20.4 quintals per acre (Rao et al., 2012). At a minimum support price of ₹2,000 per acre (Sharma, 2022), this implies a revenue of ₹35,000-41,000 per acre (\$440 to 518). Farmers in our sample in Punjab even reported lower profits, about \$300 per acre.

reduce cost-effectiveness due to payments to non-compliant farmers. Hence, the net effect of upfront and unconditional payments on compliance and cost-effectiveness is ambiguous.

Motivated by these observations, we conducted a randomized controlled trial in 171 Punjabi villages during the 2019 rice growing season to compare the efficacy of standard PES and partial upfront PES. We compare three farmer groups: those who did not receive a contract (control), those who received a contract with payment conditional on verification that the farmer did not burn (standard PES), and those who received a contract with a partial upfront payment that was (explicitly) unconditional on compliance, with the remainder conditionally paid after verification (upfront PES).<sup>6</sup>

Contract take-up was comparable and relatively high across treatment arms (72%). Our main finding is that, despite lower conditional payments, upfront PES led to 10 percentage points higher contract compliance than standard PES; this represents a doubling of the compliance rate. Remote sensing estimates of burning are consistent with the contract compliance results, showing a roughly 10 percentage point lower rate of burning among farmers offered upfront PES versus standard PES. The remote sensing measure also reveals that standard PES had no effect on burning when compared to the control group. This indicates that standard PES payments were inframarginal, i.e., paid to farmers who would not have burned even without PES. The upfront PES effect size corresponds to a 50-80% higher rate of not-burning than in the standard PES arm or control group. Consistent with the remote sensing results, in our endline survey, farmers in the upfront treatment arm were 9.5 percentage points more likely than those in the control group to report using balers (equipment used to bundle residue that has been removed from the field), while farmers in the standard PES treatment arm reported no increase in the use of balers or other “crop residue management” equipment.

Why did partial upfront contracts outperform standard PES contracts? An analysis of heterogeneous treatment effects using (pre-specified) baseline measures of generalized liquidity constraints and distrust is uninformative. Recognizing that generalized measures are imperfect proxies for specific PES-related beliefs and constraints, we also examine farmer

---

<sup>6</sup>Our design has subtreatments that vary specifics of the standard or upfront PES contract, but our primary empirical specification pools across subtreatments, as described in our pre-analysis plan.

responses to endline survey questions about the role of cash constraints and trust in determining their PES program response. Farmers assigned to the upfront PES treatment have 6.8% higher trust that contract payments will be made than those assigned to standard PES.<sup>7</sup> Around 70% of farmers say cash on hand affected their crop residue management (CRM) decisions, suggesting that this was an important overall constraint, but responses did not differ by treatment.

To compare PES costs to the benefits of reduced residue burning, we first calculate the cost per additional acre not burned for the two treatments using our remote sensing based outcome. Standard PES has no statistically significant impact on burning, and reflecting this we observe noisily estimated positive costs that are sensitive to measurement choices. Upfront PES, on the other hand, reduced burning and the cost per additional acre not burned under this arm ranges from ₹2,700 to 4,050 (or \$34 to 50). Despite the fact that a substantial portion of the farmers paid upfront burned anyway, and that some compliers were inframarginal, the estimated cost of the program is drastically lower than our rough per-acre mortality benefit estimates (\$7,600). Alternatively, we can compare the cost of pollution abatement in the agriculture sector, using PES for crop residue burning, with other abatement opportunities, specifically pollution from India’s coal-fired power plants. Again, the difference is striking: the cost per life saved from installing scrubbers in coal-fired power plants is roughly \$400,000 (Cropper et al., 2019) versus \$4,800 to 7,200 for upfront PES.

The paper is related to several literatures. First, multiple papers highlight the importance of contract design for agricultural outcomes, such as microfinance and crop insurance (Carter et al., 2017). Salient design features include timing of when the insurance or loan contract is offered (Burke et al., 2019; Fink et al., 2020; Casaburi and Willis, 2018), and how different contract features are bundled (Giné and Yang, 2009). We highlight the importance of contract design in environmental programs.

Second, conditional cash transfers are widely used to incentivize specific outcomes, and recent research tests the importance of conditionality for take up and outcomes (Baird et al.,

---

<sup>7</sup>If PES contracts were implemented as policy, repeated implementation might eventually address distrust in payments, making standard PES more cost effective over time.

2011; Akresh et al., 2013; Attanasio et al., 2015; Aker and Jack, 2021). In contrast to previous research that has focused on payment conditionality, we focus on payment timing and demonstrate that partial upfront payment during enrollment can improve compliance with a conditional contract.<sup>8</sup>

Third, while PES is widely used and studied, causal estimates of its impact, particularly comparisons of alternative PES program designs, are scarce. Exceptions include Jayachandran et al. (2017), who find that a PES program successfully reduced deforestation in Uganda, and Jack (2013) and Oliva et al. (2020), who show that program design affects cost effectiveness of afforestation contracts. While PES programs have been used to address environmental externalities associated with land use, such as deforestation, they have rarely been applied to agricultural burning, a major source of both local and global pollution. Important exceptions include Edwards et al. (2020), who find no impact of a bundled intervention of community-level training including payments to village governments for forest fire prevention, and Kramer and Ceballos (2018) who find that conditioning agricultural insurance payouts on not-burning in India lowers burning, but also insurance coverage. We contribute the first evaluation of the impact of alternative PES contract structures on efficacy and cost-effectiveness in crop residue burning.

Finally, a growing literature investigates the causes and consequences of crop residue burning (Behrer, 2019; Garg et al., 2021; Pullabhotla, 2018; Graff Zivin et al., 2020; Rangel and Vogl, 2019; Dipoppa and Gulzar, 2022). A smaller number of papers test burning-reduction policies include Edwards et al. (2020) and Kramer and Ceballos (2018); both vary incentives for burning in the context of bundled interventions. Our focus, instead, is on contract design. We leverage novel data from a new remote sensing model to measure crop residue burning (see Walker et al. (2022) for further detail), which is better suited to detecting plot-level changes in burning than existing measures of active fires, burn scars or smoke (Balboni et al., 2021; Behrer, 2019; Edwards et al., 2020; Rangel and Vogl, 2019; Jayachandran, 2009).<sup>9</sup>

---

<sup>8</sup>Evidence from other settings supports the notion that the timing of transfers can affect program outcomes, because of liquidity (Coffman et al., 2019) or other channels.

<sup>9</sup>Existing remote sensing measures of fires have historically relied on high frequency but low spatial resolution sensors, such as MODIS, (e.g., Vadrevu et al. (2011); Liu et al. (2019)). Newer sensors offer higher spatial resolution but less frequent observation, which potentially miss some crop residue fires due to

## 2 Background and Study Design

### 2.1 Crop residue burning and policy responses

About 80% of the planted area of Punjab, India’s granary, is cultivated using an annual paddy rice-wheat dual crop system. Rice is farmed from June to October (Kharif) and wheat from November to April (Rabi). The introduction of mechanized harvesting in the 1980s resulted in widespread adoption of the dual crop system, but it also created a need to manage waste on the field: mechanized rice harvesting leaves 8 to 12-inches of stalk, representing over 2.5 tons of residue per acre of paddy rice (Jain et al., 2014). In a 2019 listing survey with farming cooperative members in our two study districts, *all* farmers reported using a combination of mechanized harvesting techniques that necessitate residue removal.

Controlled burning has gradually emerged as the primary method used by Punjabi farmers to manage crop residue. Appendix Figure A.1 shows a rising incidence of fires across Punjab as a whole, as well as in our two study districts of Bathinda and Faridkot, using satellite imagery spanning 2000-2018 (Distributed Active Archive Center, 2018). Burning remains high, despite reasonable levels of knowledge of CRM; in our baseline survey, nearly 60% of farmers reported awareness of and use of CRM alternatives to burning. While cost is the primary reason for farmers’ preference for burning, they also reported that renting CRM equipment from a cooperative or custom hiring center would take around a week during peak season, potentially delaying Rabi sowing. Furthermore, the majority of farmers who were familiar with CRM alternatives expressed concern about the perceived negative effects on agricultural productivity.<sup>10</sup>

Recognizing the negative pollution externalities from residue burning, the Indian Penal Code makes residue burning a punishable offense (Section 188). A 2015 court judgement banned residue burning and directed North Indian state governments to fine farmers who did so, with fines ranging from ₹2,500 to ₹15,000 depending on the farmers’ landholdings

---

their short visual signature (e.g., Badarinath et al. (2006); Singh et al. (2021)). Planet Labs high-resolution temporal and spatial imagery helps us overcome this tradeoff. See Walker et al. (2022) for additional details.

<sup>10</sup>Agronomic evidence suggests that CRM may indeed lower productivity in the short run by immobilizing available nitrogen in the soil. In the long run, however, incorporating residue into the soil may increase organic content and available nutrients, improving productivity (Sarkar et al., 2018).

(Bhuvaneshwari et al., 2019; National Green Tribunal, 2015).<sup>11</sup> Penalty-based policies have had limited impact due to agricultural lobby opposition and insufficient enforcement. A second set of policies subsidizes *in-situ* CRM alternatives (*in-situ* techniques either pull up and mulch the stalk or leave it standing). In 2017, the central government announced a two-year \$144.3 million program for Punjab, Haryana, and Uttar Pradesh. The funding subsidized equipment such as a new seeding machine known as the Happy Seeder, which sows directly through the paddy residue, and the Super Straw Management System, which chops residue. The subsidy did not cover *ex-situ* equipment that removes the residue from the field, such as using equipment (or labor) to pull up and gather the straw, then using another piece of equipment (a baler) to bundle it into bales.<sup>12</sup>

Even with the subsidy scheme in place, the cost of CRM equipment rental remains high for farmers. Farmers typically rent the equipment from hiring centers or agricultural cooperatives, which qualify for an 80% discount on equipment purchases.<sup>13</sup> According to our baseline survey data, the median rental cost for a Happy Seeder was ₹1,250 per acre, with total out of pocket costs of CRM alternatives to burning, including equipment rental, of about ₹3,000 per acre. Farmers may prefer *ex-situ* methods because they are cheaper (e.g., renting a baler is around ₹1,000 per acre, even without a subsidy in place) or because they are perceived as less damaging to yields than *in-situ* methods.

To summarize, the policies that have been implemented to address residue burning have been largely ineffective to date. This motivates our focus on a more flexible alternative that aligns incentives: subsidizing not-burning through payments for ecosystem services (PES). We now describe our research design.

## 2.2 PES contracts

We experimentally compare the effectiveness of alternative PES contract designs for reducing crop residue burning to a status quo (of unenforced fines and insufficient equipment subsidies) control group. The treatment arms are summarized in Figure 1.

---

<sup>11</sup>The National Green Tribunal ruling applied to Rajasthan, Uttar Pradesh, Haryana, and Punjab.

<sup>12</sup>Baled straw is often used as an industrial heat source, displacing fossil fuel combustion.

<sup>13</sup>Individuals can purchase equipment at a 50% subsidy, after which a Happy Seeder cost about ₹40,000 (\$570), but few small- and medium-sized farmers own them.

Our first treatment arm implements a standard PES contract, with payments contingent on not burning and paid after compliance is verified. (We discuss how contracts are monitored and enforced later in this section.) Based on discussions with the Punjab government, our base contract sets payment at ₹800 per acre. To change behavior, the payment needs to cover the marginal cost of CRM relative to burning, not the full cost of CRM. Burning may take time or require some material inputs, and some farmers may perceive it as detrimental to soil fertility. The variability in whether farmers burned in the status quo (8-20% did not burn in our control group, according to our two remote sensing estimates) indicates heterogeneity in farmers' reservation price to switch away from burning; some farmers have a negative (or 0) reservation price, but the vast majority have a positive reservation price, which likely varies considerably. To assess the importance of payment levels, we introduce a variant on the standard PES contract that pays twice as much as the base contract, or ₹1600 per acre not burned.<sup>14</sup>

The standard PES contract pays out only after the desired behavior or action has occurred (i.e., not burning). Farmers may not undertake a costly action in anticipation of a future payment if they do not trust the principal to follow through with the payment or if they lack cash on hand to carry out the action required for compliance. Both distrust and liquidity constraints are plausible barriers to compliance in our study setting. At baseline, only 13% of farmers said they had complete trust in the government, with even lower levels of trust in NGOs, about 7%. Less than half of the sample had ₹5,000 in savings and the majority said that it would be somewhat difficult or difficult to access a ₹5,000 loan. Our second treatment arm was designed to address these constraints by offering partial payment upfront, with the remainder paid conditional on contract outcomes. The sum of the (potential) upfront and ex post payments was held fixed at ₹800 to match our base contract. We evaluate two variants of the upfront PES treatment, which vary the share paid upfront.

While upfront payments could, in principle, be recouped from a participant who does not

---

<sup>14</sup>In November 2019, (after our intervention) the federal court ordered the Punjab government to pay farmers ₹100 per quintal of paddy, or about ₹2,500 per acre, conditional on self-reported not burning. Concerns regarding farmer's self-declarations that they did not burn led to the program's suspension a few weeks later. In our endline survey, about 30% of the sample were aware of the government program, of which about half reported applying to the program. The other half reported learning about the program after having begun residue management. 80% of farmers who were aware of the program did not anticipate timely PES payments.

comply, imposing such conditionality is challenging in practice (e.g., because participants are poor). Our contract explicitly made the upfront payment unconditional. Because the upfront component reduces the conditional payment amount — the farmer’s incentive to comply — this feature could reduce compliance. In addition, because unconditional payments will be made to some farmers who then do not comply, the upfront payment could reduce PES cost-effectiveness, even if it increases compliance.

Farmers’ participation in all treatments was voluntary, and noncompliance with the PES contract was only penalized through non-payment. This raises two more concerns. First, some people who complied with the contract might have undertaken the desired activity even in the absence of the contract, i.e., the payments are inframarginal to their non-burning. Second, because there is no penalty for non-compliance, many farmers may enroll and later renege, increasing implementation costs particularly when some payment is offered upfront (Oliva et al., 2020). Our study design allows us to evaluate these concerns by measuring “additionality” (i.e., whether contracts reduce burning relative to status quo) as well as evaluating the cost effectiveness of alternative PES contracts.

## 2.3 Sample

We chose Bathinda and Faridkot as our two study districts in Punjab because both have high rates of burning and little activity to encourage CRM adoption by other organizations.<sup>15</sup> We limit our sample frame within these districts to villages with functioning farmer cooperatives, and within these villages, to farmers who were cooperative members (as of August 2019). From among the 393 villages in our sampling frame, we chose the 300 with the most members for screening.

Initial farmer eligibility screening was done by phone. A farmer was eligible if he or she grew between 2 and 12 acres of paddy, planned to harvest after the second week in October and plant the winter (Rabi) crop, and employed farm equipment indicative of burning (namely, used a reaper or did not use a chopper) in the previous year. The last criterion

---

<sup>15</sup>According to the Visible Infrared Imaging Radiometer Suite (VIIRS) satellite data (Distributed Active Archive Center, 2018), Faridkot had about 1.9 fires per square km in 2018, ranking sixth highest in the state, while Bathinda had 1.7 fires per sq km, ranking ninth. We present total fires from this data source in Appendix Figure A.1.

means that our sample has higher burning than average; by minimizing inframarginal payments through sample design, we increased statistical power to detect changes. We chose 176 villages with at least 18 eligible households for an in-person baseline survey.<sup>16</sup> Villages with fewer than six completed baseline surveys were eliminated, resulting in a final sample of 171 villages and 1668 respondents.

In February 2020, we conducted a census in four study villages to assess sample representativeness. 70% of farmers reported being cooperative members. Census farmers, like study farmers, were nearly universally engaged in paddy-wheat cultivation. Since we only enrolled farmers cultivating 12 acres or less (a criterion that 80% of census farmers met), study farmers cultivated less land than census farmers (5.3 acres versus 7.7 acres). The fact that our sample was screened to include farmers who were more likely to burn may explain why study farmers were 29 percentage points less likely to report knowledge of alternatives to burning.

## 2.4 Randomization and contract implementation

We randomly assigned villages to one of four treatments or the control group. Figure 1 summarizes the sample size per arm. Randomization occurred while the listing and baseline surveys were ongoing.<sup>17</sup> Following a baseline survey, eligible farmers in treatment villages received a follow-up visit and were offered a PES contract, on average 5.6 days later. If they could not be located or did not have a bank account, they were not offered the contract.<sup>18</sup>

Farmers received a basic program description as part of the contract offer (see Appendix C). The contract (offered by J-PAL) corresponding to their treatment arm was then shown to interested farmers, and the terms were read aloud by the enumerator.<sup>19</sup> Farmers who agreed

---

<sup>16</sup>The baseline prioritized villages with the largest number of eligible households based on listing data. Baseline data collection stopped once the target sample of 176 villages was reached. Enumerators moved down a randomly ordered eligible list until 16 surveys were completed or the list was exhausted.

<sup>17</sup>Initial assignment was stratified on district, below versus above median number of eligible households based on phone listing survey, baseline survey completion in the village, and listing survey completion in the village. We include a fifth strata of 15 villages that were randomly added to the different arms to supplement the sample size. These were villages where listing survey had been covered between six to 17 households. The order of listing was randomized, and the baseline and treatment implementation followed this order. Baseline surveyors didn't know a village's treatment status.

<sup>18</sup>Contract payments were electronic, with account information only collected from treatment farmers.

<sup>19</sup>A sample contract for the ₹800/acre arm with no upfront payments is included in Appendix D.

to the contract terms received an information handout outlining the terms and conditions, as well as procedures for monitoring and verifying burning outcomes. During the enrollment visit, enumerators recorded whether the farmer was offered the PES contract in person and, if not, why (e.g., household could not be found, no bank account), and whether the farmer took up the contract. A farmer's entire paddy acreage (as physically measured by the surveyors at baseline) was automatically enrolled if the farmer took up the contract. The maximum amount a farmer could be paid under the contract was ₹16,000 for farmers in the ₹1600 per acre arm and ₹8,000 in the other treatment arms.<sup>20</sup> Farmers in the upfront PES arm received the upfront portion of their payment via direct bank deposit 2-3 days after enrollment.

Contract monitoring and enforcement required verifying that none of the paddy plots were burned. To detect burning or its absence, project enumerators had to visit the plot during the short window between when the farmer removed the residue (via CRM or burning) and when the farmer tilled the soil for planting the winter (Rabi) crop.<sup>21</sup> Because monitoring was required during this farmer-specific window of a few days, the farmer was responsible for contacting J-PAL after managing residue and at least four days before sowing the winter (Rabi) crop. Up to two monitoring visits could be requested if, for example, different plots had different sowing schedules. When farmers called in, appointments for monitoring were made, and the map of all study plots collected at baseline was given to the monitor.<sup>22</sup>

Visual inspection at the right moment can tell if a field was burned. The enumerator was required by the monitoring protocol to observe and record multiple observations on each plot, including burned straw or residue, grey or black ash on the soil, burned root residue, burned grass or weeds on the plot boundaries, and burned leaves or tree branches on the plot boundaries. Enumerators were told to inspect the plot perimeter and walk onto each plot and inspect the soil. Farmers were not immediately informed of the monitoring results after it was completed. Monitoring staff did not know specifically how the different data they

---

<sup>20</sup>Farmers eligible for the study cultivated 12 or fewer acres of paddy. For farmers with more than 10 acres of paddy, about 7% of the sample, the value of the contract per acre is constrained by the cap.

<sup>21</sup>Prior to the completion of CRM, a monitoring visit could not rule out future burning. After tilling, visual signs of burning become less obvious.

<sup>22</sup>Placing the onus for monitoring on the farmer may lower compliance. However, it increases monitoring accuracy since the precise timing for verifying absence of burning varies from mid-October to late November. Farmers who had not yet requested monitoring were contacted in the third week of October with a reminder that it was the farmer's responsibility to request monitoring.

recorded would be aggregated to determine contract compliance. The observations were combined into a single farmer-level compliance metric, and payments were made on a rolling basis, approximately 2-3 days after monitoring. Any burning was a contract violation.

## 3 Data

Figure 2 presents the agricultural season for the paddy-wheat cropping cycle in Punjab, as well as the data collection timeline. Our data collection is focused on measuring impacts on farmer behavior. Because only a small proportion of farmers in each village participated in our study (on average, 9.8 farmers per village), we do not seek to detect treatment effects on village-level outcomes (such as air quality).

### 3.1 Survey and contract compliance data

**Baseline survey** We conducted baseline surveys with the identified person on the cooperative member list in October 2019. This person was in charge of household agricultural decisions in more than 90% of households. We collected data on demographics, agricultural production, income and credit constraints, trust in organizations, and barriers to CRM. Farmers listed all plots where paddy was grown, and accompanied the enumerator to each plot to collect geocoded perimeter measurements. The latter form the basis for monitoring treatment farmers’ contract compliance and for linking satellite imagery to farmers for both the treatment and control groups.<sup>23</sup>

**Endline survey** We conducted a phone-based endline survey in June 2020, following the completion of the winter (Rabi) harvest.<sup>24</sup> The survey gathered information about self-reported field burning and CRM techniques. We also gathered information on agricultural production and income over the previous two seasons (Kharif 2019 and Rabi 2020). Section

---

<sup>23</sup>At each plot, the enumerator walked the perimeter of the field using a mapping application on a GPS-enabled tablet. We drop 47 fields (1.6 percent) where either the field ID was missing from the geospatial data or two fields completely overlapped. Because the plot was measured before treatment was assigned, any measurement error in plot inventories or field perimeters should be orthogonal to treatment.

<sup>24</sup>The contract rollout and monitoring were completed prior to COVID-19 pandemic. However, the in-person endline survey, scheduled for April 2020, had to be switched to a phone-based survey.

4.1 reports attrition between the baseline and endline surveys and balance tests.

**Contract take-up and monitoring data** At the time of contract offer, we record farmer enrollment decisions and non-enrollment reasons. We also note whether a treated farmer requested monitoring. We observe monitoring results for those who did, including the distinct plot-level signs of burning described above. These were combined to produce a binary burning outcome: A farmer complied with the contract if none of his or her plots show signs of burning. A total of 187 farmers and 319 plots were observed.

**Spot check data** We conducted spot checks on one randomly selected field for 50% of farmers in each sample village. The spot check data are used as training inputs to the remote sensing model described below. The spot check protocol was similar to that for monitoring with a few exceptions. First, only one randomly selected plot was visited per farmer. Second, because the farmer did not accompany the enumerator, all observation occurred outside of the field. Third, unlike the monitoring visits that occurred when the farmer informed us they had removed their residue but not yet tilled the soil for their winter (Rabi) crop, spot checks could not be synchronized with the farmer’s specific harvest and CRM timing.<sup>25</sup> Overall, we conducted 720 spot checks in November 2019.

## 3.2 Remote sensing measures

**Satellite data** The data on take-up and monitoring are informative of how many farmers signed up for the contract and were verified as not burning, but not the rate of burning among non-monitored farmers. Some farmers in the control group may not have burned, and some farmers in the treatment group who did not enroll or did not call for monitoring may also not have burned. Thus, our analysis also uses a measure of burning constructed from high-resolution satellite imagery from two sources, PlanetScope and Sentinel-2.<sup>26</sup> PlanetScope

---

<sup>25</sup>We do not use spot check data as a primary outcome because to have sufficient statistical power, we would have had to conduct repeated visits to address the challenge of observing the field after harvest but before tilling. Repeated monitoring might have also directly affected behavior.

<sup>26</sup>PlanetScope has a 3 meter resolution and Sentinel 20 meter. Other commonly used sensors such as MODIS and VIIRS are available at lower resolution only, 375 meters to 1 kilometer, and therefore inappropriate for the small fields we study.

data is higher frequency (roughly every 2-3 days) and is less likely to miss a burning event. This feature is important because burned fields become observationally similar to unburned fields once the soil is tilled for Rabi planting. Appendix Figure A.2 depicts this in Sentinel-2 imagery for one study field. The absence of a persistent visual signature of burning is particularly problematic in PlanetScope’s visual and near-infrared bands. Sentinel-2 data are collected at a lower frequency (every week to 10 days) but, unlike PlanetScope, they provide information in the mid-infrared range, which helps separate burned from unburned fields. Thus, the imagery from the two sensors complements one another.

**Data processing and classification** We train a random forest (RF) model with labels (burn or no burn) from the monitoring and spot check data, using pixel-level data from the two sensors; Walker et al. (2022) describes the data processing and machine learning model). Our labeled set (of 681 fields) includes burn labels (positives) from the spot check and monitoring data and no-burn labels (negatives) only from the monitoring data.<sup>27</sup> The RF model outputs a pixel-level continuous prediction score ranging from 0 to 1, which represents the proportion of decision trees that the model classified as burned. We avoid over-fitting by holding out each field (consisting of many pixels) from the training set, obtaining a prediction for each held-out pixel. To aggregate pixel-level data to a field-level burning outcome, we average the predicted score across pixels in a field (omitting perimeter pixels) and then choose a threshold above which a field is classified as burned. To generate binary burn estimates for the entire data set, we apply the mean of the trained RF models (recall we have one trained model for each of the fields in the training set, given the procedure to avoid over-fitting) to unlabeled pixels, aggregate and apply the classification thresholds as described in the next paragraph. For consistency with other contract outcomes (a higher value is an environmental improvement), we invert the burning classification when estimating treatment effects. At the farmer level, this outcome equals zero if a farmer is predicted to have burned any of his fields.

We present two alternative thresholds: (1) equalize prediction accuracy for burn and no-burn labels (training data), which also equalizes type I and type II errors or sensitivity and

---

<sup>27</sup>We exclude negative labels collected during spot checks because they indicate no burning in the days immediately preceding the spot check visit but provide no information about burning outside that window.

specificity (*balanced accuracy*), and (2) maximize overall model accuracy (*max accuracy*). Because burning is more common in our data than not burning, the max accuracy measure improves overall accuracy at the expense of accuracy in predicting no-burns, i.e., by relaxing the threshold to classify more fields as burned. This, however, also increases the likelihood of false negatives (burns). The balanced accuracy measure avoids this problem by balancing the rate of false positives and false negatives, but at some (relatively minor) cost to overall accuracy (by increasing the scope for false positives by classifying fewer fields as burned). The tradeoff between these two measures affects the control group mean burning rate: predicted burning is higher in the max accuracy measure than the balanced accuracy measure by construction. These differences only change treatment effects if the fields in the part of the distribution between the two thresholds are disproportionately from the treatment or control groups.<sup>28</sup>

The RF model is trained using negative labels that are only available for the treatment group (and positive labels for both treatment and control groups). This could introduce bias into the classification if the spectral signature of not-burning is affected by treatment; if not-burning looks the same in treatment and control, this is not an issue. As one check on potential bias, Appendix Figure A.3 shows the distributions of the continuous random forest model output using fields not in the training set. Both for fields classified as burn and those classified as no-burn, the distributions are similar in the treatment and control groups. Formal statistical tests for equal distributions, conditional on classified burning status, confirm that there is no statistical difference.

The balanced accuracy model has an overall accuracy of 78 percent (see Table A.1), while the max accuracy model does marginally better (by definition) at 82 percent. The difference is due to 425 fields or 203 farmers (12% of the sample) being classified as no-burn under the balanced accuracy threshold and burn under the max accuracy threshold. 11% of the control group, 10% of the standard PES treatment and 15% of the upfront PES treatment fall between the thresholds, i.e., moving from balanced accuracy to max accuracy re-assigns their no-burn outcome from 1 to 0.

---

<sup>28</sup>Given that the farmer-level outcome is set to one if a farmer burns any of his fields, impacts on farmer-level burning outcomes may be more pronounced than at the field level.

### 3.3 Burning and farmer heterogeneity measures

**Burning measures** We use multiple data sources to measure farmer residue burning, and consider ancillary outcomes that are likely related to burning. To begin, we use contract compliance data to create an indicator for whether a farmer requested monitoring and, if so, whether the farmer was found not to have burned during the monitoring visit. This outcome allows us to compare the treatment effects of standard PES versus upfront PES. However, because we do not measure this outcome in the control group, we cannot use it to compare impacts to counterfactual burning.

Second, we use remote sensing measures that construct a predicted not-burning measure for all farmers. We present two versions of the remote sensing model, as described in the previous sub-section, which rely on the same underlying imagery and machine learning models, but differ in the threshold used to convert the continuous score at the pixel level into a field-level binary burn/no-burn outcome.

Finally, we rely on endline survey data for measures of CRM practices among treatment and control farmers, which include the primary alternatives to burning: balers (*ex-situ*) and Happy Seeders (*in-situ*).

**Farmer heterogeneity measures** Following our pre-analysis plan, we use baseline data to create a distrust index and a financial constraints index, which are the two barriers that motivated us to test the upfront PES contract. The survey questions used to create all heterogeneity indices and their aggregation into binary variables are discussed in Appendix B. Because our study population had no experience with PES programs, and over 40% had no experience with CRM equipment, the survey questions focused on farmer trust in general and overall financial constraints related to agriculture. Both baseline indices, thus, capture generalized beliefs rather than specific beliefs related to choices around residue burning. For instance, when measuring financial constraints, we asked farmers if they could access savings or loans for agricultural equipment for two different amounts (₹5,000 and ₹10,000.). Trust was measured using questions that asked farmers their level of trust in people in general, and specific groups (the Punjab Government, their village Panchayat, cooperative society, NGOs, and financial institutions like banks and insurance companies). In contrast, the

endline survey directly asked treatment group farmers about trust in the PES program, and financial constraints specific to CRM.

We also construct indices of CRM equipment access, which may affect overall PES program take-up or compliance (we did not hypothesize they would differentially affect compliance with standard versus upfront PES). We construct three sub-indices to measure different access barriers: informational barriers (i.e., awareness of alternatives to burning and knowledge of where to rent them), CRM equipment access barriers (including delays), as well as negative beliefs about the impact of CRM equipment on soil health and agricultural yield.

## 4 Results

### 4.1 Estimation strategy

We estimate the following equation:

$$y_{ij} = \alpha + \beta StandardPES_j + \gamma UpfrontPES_j + \psi X_j + \epsilon_{ij}$$

where  $y_{ij}$  denotes an outcome for farmer  $i$  in village  $j$ , and  $StandardPES_j$  and  $UpfrontPES_j$  are binary variables that take the value 1 if village  $j$  is assigned to the standard PES treatment and the upfront PES treatment, respectively.  $X_j$  are strata fixed effects. Following our pre-analysis plan, and to increase statistical power, we pool treatment variants (different payment levels in  $StandardPES_j$  and different proportions paid upfront in  $UpfrontPES_j$ ). Standard errors are clustered at the village level.  $\beta$  is the effect of being assigned to the standard PES treatment, and  $\gamma$  the effect of assignment to the upfront PES treatment (each relative to the control group).

Table 1 presents summary statistics and four types of balance tests: for the treatment (pooling all treatment arms) versus control group, for standard PES (pooling ₹800 and ₹1600 per acre) versus the control group, upfront PES (pooling 25% upfront and 50% upfront groups) versus the control group, and for upfront PES versus standard PES. In each comparison self-reported burning in 2018 is balanced. We observe slight imbalance in measures of land size and CRM indices; the p-value of the joint F-test is 0.48 between treatment

and control.

Table 1 also provides more details on our respondents. They have significant farming experience and produce on about five acres of land, on average. The majority of household income comes from agriculture, with a control group mean agricultural profit of ₹114,000 (median is ₹58,000).<sup>29</sup> At baseline, 68 percent of farmers self-reported burning their fields in the previous year, though the actual value is likely higher given our screening criteria. Less than half of the sample, 48%, had previously signed a written contract.

We have no attrition for our main outcomes of PES compliance and remotely-sensed burning. For the endline survey, Appendix Table A.2 shows that a reasonably high response rate for a phone survey (greater than 80%) but with some differential attrition; the treatment group was about 5 percentage points less likely to respond. However, there is no difference in attrition between the standard and upfront groups.<sup>30</sup> Following Lee (2009), we report both the point estimates and upper and lower bounds on our estimates for regressions using endline survey outcomes for treatment and control groups.<sup>31</sup>

## 4.2 Treatment effects

### A. Did farmers take up the PES contract offers?

In Table 2, we examine differences across treatment arms in whether the surveyor found and offered the farmer the PES contract, as well as whether the farmer was eligible for the offer (i.e., he had a bank account and had not yet harvested his paddy). These outcomes are zero by construction in the control group, and they are determined for treatment farmers before they learned the details of the contracts. Farmers were found in treatment arms at a similar rate – 87.9% in the upfront PES treatments versus 88.5% in the standard PES treatment

---

<sup>29</sup>The baseline agricultural profit measure helps interpret the magnitude of the contract payments; the median base contract payment of ₹800 per acre equals ₹4,000 per farmer (since the average farmer cultivates 5 acres), or about 7% of median agricultural profit.

<sup>30</sup>8% of the sample had invalid numbers, while 4.8% couldn't be contacted in eight attempts. The remaining attrition is due to: 1% of the sample didn't answer the phone, 0.12% had the wrong number, 0.59% refused to talk prior to the consent, 1.2% didn't consent to the survey, and 0.96% didn't complete the survey.

<sup>31</sup>Lee bounds entail estimating treatment effects after dropping (in turn) the observations with the lowest and highest outcomes in the less-attrited group, so that the proportion of included observations is equal across treatment and control. We trim observations from the control group within strata and include strata fixed effects in the estimation because our randomization is stratified.

(column 1). The same is true for eligibility: 83.3% of farmers were eligible in the upfront PES treatment and 84.4% in the standard PES treatment (column 2).

Next we consider program take-up, which is again zero by construction for control farmers. Take-up (i.e., whether a farmer signed the PES contract) was high, with around 72% of farmers in both treatment arms signing the contract.<sup>32</sup> Conditional on being found and being eligible, the probability that a farmer took up the PES program is very high (around 87%). This is consistent with the option value associated with the contract being high in both treatments (since farmers who choose to burn forgo the conditional payments but face no penalties). The fact that contract take-up is not higher when the PES contract includes upfront payment is surprising, but could stem from the fact that farmers were not given the upfront cash right away. They were asked for their bank account information, and funds were transferred 2-3 days later. Trust barriers might have similarly deterred take up in the two treatment arms; farmers may have objected to sharing bank account information or granting access to their plots for monitoring.

## **B. Did farmers offered PES contracts reduce their crop residue burning?**

Our first measure of not-burning is contract compliance, i.e., whether the farmer called for monitoring and in the monitoring visit was found in compliance with the contract (no fields were burned). Table 3, column 1 shows that 8.5% of farmers complied with the contract in the standard PES group. Compliance in the upfront arm is 10 percentage points higher, at 18%, and equality between the two groups can be rejected with  $p < 0.01$ .<sup>33</sup> Thus, despite similar contract take-up rates in the standard and upfront PES treatments, upfront payments make farmers twice as likely to comply with the contract.

Next, we consider our two remote-sensing based measures of whether a farmer burned any fields.<sup>34</sup> Columns 2 and 3 of Table 3 present results for the balanced accuracy and max accuracy classifications, respectively. As with contract compliance, upfront PES outperforms

---

<sup>32</sup>As shown in Appendix Figure A.4, take up rates were similar across all sub-treatments.

<sup>33</sup>Treatment effects on the outcome of whether the farmer called for monitoring (regardless of compliance) follow a similar pattern – 11% of farmers in standard PES called and there is a 10 percentage points higher likelihood of calling for monitoring in the upfront arm.

<sup>34</sup>About 18% of the sample had at least one field predicted to be burned and at least one field predicted not burned. We present plot-level treatment effects in Table A.3.

standard PES, with treatment effects that are similar across the two alternative remote sensing measures. Relative to the control group, upfront PES increases not-burning by 8-11.5 percentage points. In contrast, the effects of standard PES relative to the control group is indistinguishable from zero.<sup>35</sup> The latter result implies that standard PES payments were inframarginal: these farmers would not have burned their fields even if the program did not exist.

The two remote-sensing models differ in their estimate of the not-burning rate in the control group, which is 20% in the balanced accuracy classification and 9% in the max accuracy classification. Appendix Figure A.5 shows the control group mean and estimated treatment effects as the threshold is varied from a lower bound that classifies all true no-burns as no-burns to an upper bound that classifies all true burns as burns. The treatment effects are less sensitive to the choice of threshold than is the control group mean (top panel). The variability in the estimated control group mean does not affect the conclusion that the upfront PES arm was effective at lowering burning, but it does bear on whether the results imply that some farmers left money on the table. With the higher control group mean estimated in the balanced accuracy model, the implied rate of not-burning in the upfront villages is 31%, implying that some farmers in the upfront arm who did not burn also did not call for the conditional payment.<sup>36</sup> The max accuracy results, on the other hand, imply that all farmers who did not burn received the conditional payment, so farmers did not leave money on the table.

Appendix Figure A.4 disaggregates treatment effects by the four treatment arms. The point estimates for all outcomes other than contract take-up are larger for upfront PES arms. Paying more in the standard PES variants (₹1,600 versus 800) increased the point estimates on compliance and remote sensing based measure, though the difference between the two standard PES variants is indistinguishable from zero. In both cases, compliance with the ₹1,600 arm is lower than with either upfront arm. The latter result is striking given that the upfront contract only pays ₹800 per acre. Across the two upfront arms (25% upfront

---

<sup>35</sup>Treatment effects estimated on our subsample for which we have spot check data are similar in magnitude (see Appendix Table A.4), but with considerably lower statistical power and a (mechanically) higher control group mean given that not all burns were detected through a one-time surprise field visit.

<sup>36</sup>In the endline survey, some farmers reported losing the number to call for monitoring or forgetting when they were supposed to call.

versus 50% upfront), it is theoretically ambiguous which should perform better, as increasing fraction paid upfront meant a lower reward for compliance; we find similar effects for the two variants.<sup>37</sup>

In Table 4, we analyze treatment effects on the main *ex-situ* and *in-situ* alternatives to burning: baler and Happy Seeder use, respectively. Increased use of balers – by 10 percentage points – can explain all of the difference in compliance between the treatment arms. We see no consistent or detectable measurable changes in the use of the Happy Seeder. Consistent with the null effect of standard PES on our remotely sensed burning measure, we see no difference in CRM usage in the standard PES arm relative to the control group, suggesting that standard PES had no impact on residue management behavior. In the second panel, we present Lee bounds to account for differential attrition by treatment status in the endline survey (from which we derive these results). Consistent with the point estimates, we only see a statistically significant increase in baler use for the upfront PES group (between 8.8 and 14.5 percentage points, the lower and upper bounds, respectively).

Two important factors cited by farmers as arguments in favor of residue burning are reducing delays between harvesting and sowing the next crop and agricultural yields. In our setting, the significant upfront payouts in the upfront PES treatment may have directly affected agricultural outcomes. Appendix Table A.5 present treatment effects on crop yield for rice and the winter (Rabi) crop (which is wheat for 99.6% of the sample) and on delays in sowing the winter (Rabi) crop. Neither treatment impacted these outcomes.

### 4.3 Why did upfront payments increase farmer PES compliance?

Upfront PES reduces burning more than standard PES. We now examine why partial payment upfront may boost contract effectiveness.

Panel A of Table 5 presents heterogeneous treatment effects by pre-specified baseline indices: a distrust index and a financial constraints index.<sup>38</sup> These indices capture general-

---

<sup>37</sup>The results across the two upfront arms diverge more for the max accuracy remote sensing based outcome than for either the compliance or balanced accuracy outcomes, though differences in the coefficients fall well within the standard errors around all of the estimates.

<sup>38</sup>We also use a generalized random forest model to identify variables that explain heterogeneity in the treatment effect of the ₹1600 Standard PES treatment relative to the control. The four variables that this procedure determines are the most important one are all elements in our trust index. However, when used

ized distrust and financial constraints faced by farmers, rather than CRM or PES-specific constraints. In both cases, we use a binary measure for being above the index’s median, or highly constrained. Columns 1 and 2 present results using contract compliance as the outcome, and Columns 3 through 6 using remote sensing measures of burning as the outcome. We do not find any differential impact of the upfront program by either heterogeneity index on any of the outcomes.<sup>39</sup>

In addition, in the endline survey, we asked a subset of farmers (63% of the sample) in the standard and upfront arms about distrust and financial constraints related to CRM decisions and the PES program.<sup>40</sup> To gauge trust in the PES program, we asked: “When I was deciding how to manage my residue during Kharif 2019, I was sure that J-PAL would return and pay me the amount owed to me if I did not burn.” We create a binary variable that equals 1 if farmers answered yes (low constraint), and 0 otherwise. To test for cash constraints in CRM decisions, we asked farmers how much they agreed with the statement “When I was deciding how to manage my residue during Kharif 2019, shortage of cash limited what methods I could choose for residue management.”<sup>41</sup> We create a binary variable that equals 1 if they answered “Shortage of cash was not at all important”, “not very important” or “somewhat important” and 0 otherwise.<sup>42</sup>

Panel B of Table 5 presents results using these two endline variables as outcomes.<sup>43</sup> Farmers in the upfront arm are nearly 7 percentage points more likely than farmers in the standard PES arm to say that they trusted that the conditional payment would be made if

---

in a second step to test heterogeneity in the treatment effect of the Upfront PES arms relative to the ₹800 Standard PES treatment, they are inconsistently signed and imprecisely estimated.

<sup>39</sup>Like all heterogeneity on observables, this null result could mean that the generalized measures are not relevant or that our baseline measures lack sufficient sample variability to pick up an effect. Other mechanisms may also be relevant, such as reciprocity. We are guided by our pre-analysis plan, but note that reciprocity seems unlikely mechanism the high cost of contract compliance and the lack of differential endline survey participation by treatment arm.

<sup>40</sup>We ask these questions of only a subset of farmers because we reduced the survey duration partway through the sample.

<sup>41</sup>Only contract signers were asked about trust, but both were asked about cash shortages. To keep the sample consistent, we only study contract signers here, but results on monetary constraints are similar if we include all respondents.

<sup>42</sup>The other options were that shortage of cash was very important or extremely important in determining CRM decisions. Alternative classification which classifies cash shortage as being unimportant if the respondent answered “Shortage of cash was not at all important” or “not very important” lead to qualitatively similar results.

<sup>43</sup>Note that since there is no differential attrition in the standard versus upfront arms for the endline survey, Lee bounds are not required.

they complied. Recall that the difference in compliance between the two contract types is about 10 percentage points, so the increase in trust represents an economically significant effect.<sup>44</sup> We interpret this result as suggestive evidence that instilling trust was a mechanism by which upfront PES was more effective than standard PES.

In contrast, farmers in the upfront arm were not more likely to report cash shortages being unimportant for CRM decision-making. However, the absence of evidence here does not necessarily imply the absence of an effect of upfront payments on the ability to pay for CRM equipment. For example, the upfront amount (which could cover less than half the cost of baler rental) may have been too low to meaningfully ease this constraint.

Appendix Table A.6 presents additional pre-specified heterogeneous treatment effects. These include information constraints about alternatives to burning, barriers to accessing CRM equipment, and beliefs about the negative impact of non burning alternatives on yields, pest prevalence, or soil health. These heterogeneity results are estimated without the control group, where the outcome is zero by construction. The correlation between the heterogeneity variable in the pooled treatment group and compliance can thus be interpreted as the heterogeneous treatment effect. Farmers with higher information constraints and more negative beliefs about burning alternatives are less likely to comply with PES, pooling all of the treatment arms.

## 5 Program costs and benefits

We set up a cost effectiveness comparison across treatments in Table 6. Column 1 shows the treatment effects for farmer-level payments (zero by construction in the control group). We exclude the cost of monitoring contract compliance because it is sensitive to program scale and specific protocols around monitoring. Monitoring costs for our program were roughly ₹300/field or less than ₹100/acre, which is small in comparison to the PES payments. The results show that upfront PES pays out more, both because more people comply and because

---

<sup>44</sup>Note that the higher reported trust in the payment among farmers in the upfront PES treatment is not limited to the compliers in the upfront PES arms; levels of trust do not vary with compliance. In contrast, in the standard PES arms, farmers who complied – and received payment – were around 10 percentage points more likely to report a high level of trust in the payment.

farmers who burn also receive upfront payments. Columns 2 and 4 reproduce the treatment effect on the binary variable of not burning shown earlier, using the balanced and max accuracy models, respectively. Note the slightly different results across the columns, which we return to below.

Columns 3 and 5 then show the cost per additional unburned acre, calculated by dividing Column 1 estimates by the estimates in Column 2 or 4 for each treatment. (Figure A.6 shows the results by treatment arm). In the balanced accuracy results, the effect on burning in the standard PES treatment is very close to zero, resulting in a large but imprecise cost per unburned acre (column 3). Despite higher payment per acre, the upfront PES treatment remains more cost effective than standard PES, at a cost of around ₹2,695 per acre. For the max accuracy, the tradeoff between treatment effects and cost effectiveness is more apparent. For this measure, the effect of standard PES on burning (column 4) is small and statistically imprecise, but considerably larger than with the balanced accuracy measure. The treatment effect on not burning from upfront PES is also smaller using the max accuracy classification than the balanced accuracy classification. Thus, upfront PES is “only” 4 times as effective as standard PES. Because upfront PES entails 3 times as large a payment per acre as standard PES, the cost-effectiveness gap between the contract types is not as stark: Upfront PES has a cost of ₹4050 per unburned acre, compared to ₹5157 for standard PES (column 5).

Next, we compare these costs to the benefits of reducing crop burning. According to the Global Burden of Disease-Major Air Pollution Sources, crop burning in India claims an estimated 66,000 lives annually due to pollution exposure (Global Burden of Disease Working Group, 2018). Using a \$1 million Value of Statistical Life (VSL), this implies \$66 billion of annual damages. Assuming 50% of paddy is burned, the combined paddy acreage of 17.37 million acres in Punjab, Haryana, and Uttar Pradesh implies damages of \$7599/acre (₹606,800), which are over 200 times the per acre cost of reducing burning through PES with upfront payment.<sup>45</sup>

---

<sup>45</sup>We use estimates of percentage of paddy burned from Liu et al. (2020), who uses household-level data from Punjab, Haryana, Bihar, and Uttar Pradesh, using a stratified purposive sampling technique to select households representative of the village-level distribution of landholding sizes. They find that 53% of Punjab households reported burning, with lower reported burning rates in Haryana and UP (10% and 9% respectively). A lower burning rate (than 50%) would attribute the total damages to fewer acres, favoring burning mitigation even more.

To put this cost per life saved in perspective, we compare it to other pollution abatement options. Coal-fired power plants are a major source of particulate emissions in India, and installing  $SO_2$  scrubbers lowers emissions of fine particulate matter. According to the Global Burden of Disease 2018, thermal power claims 84,650 lives in India each year. Installing scrubbers avoids 72% of deaths in the first year (Cropper et al., 2019), which would save 60,948 lives. India has 204 GW of coal capacity (Ministry of Power, 2022); on average, installing scrubbers in a 500 MW plant would save 150 lives per year, and costs about \$1.2 billion over 20 years, or 60 million per year annualized. Assuming no discounting and constant benefits for the lifetime of scrubbers, the cost per life saved is around \$400,000. For comparison, the cost per life saved from our most cost effective treatment is \$4,800.<sup>46</sup> Thus, while several abatement opportunities have benefits that outweigh costs in India, residue burning reduction has the potential to save lives at a much lower cost.

## 6 Conclusion

Identifying low-cost pollution abatement opportunities allows for more efficient use of limited environmental protection budgets. Even if promising opportunities are identified, limited enforcement incentives and market imperfections, such as credit constraints or weak institutions, can undermine the efficacy of policies aimed at these abatement opportunities.

We show that crop residue burning, which has significant environmental and human health costs, can be reduced through well-designed PES payments. In particular, program design that takes institutional constraints and farmer concerns into account can significantly improve efficacy. Providing a portion of the contract payment upfront results in larger reductions in burning than providing the entire payment after participants have completed costly behavior change. Despite higher “wasted” payments (to farmers who continue to burn), PES with upfront payments is cost effective, resulting in burning reductions that provide benefits far in excess of their cost.

Scaling up PES contracts to avoid burning poses some challenges. First, the monitoring

---

<sup>46</sup>Using above assumptions, crop residue burning causes 0.0075 deaths per acre annually. Reducing one acre of burning costs ₹2695/acre, or ₹359,333 per life saved. At 75 ₹per \$, this is \$4,791 per life saved.

protocols that we implemented were not designed for scale. Viable approaches to large-scale monitoring, such as remote sensing, are likely to increase contract risk because of measurement error (though different forms of contractual risks may exist with scaled-up in-person monitoring as well). Second, equipment to manage crop residue is still scarce, and PES at scale will increase demand for this equipment, raising the cost of not burning. For example, if all farmers began renting balers, the rental price of balers would rise.

There are also reasons for optimism. The roll-out of a large-scale PES program would create incentives for innovation in better CRM equipment or rental market efficiency. Dynamic incentives — in the form of tying future eligibility to verified not burning — could reduce the cost of providing upfront payments. The need for upfront payments also might become less important as trust in being paid grows. Finally, PES programs are appealing because they can be implemented by organizations that want to reduce fires but lack the authority to levy fines. The enormity of the environmental damage caused by crop residue burning in India justifies such an investment and also highlights the need for further research to find viable solutions to this problem.

Panel D: Burning							
1(Burned paddy residue in 2018)	1576	0.684	0.465	0.025 (0.034)	0.044 (0.037)	0.006 (0.039)	-0.037 (0.035)
P-value of joint F-test				0.475	0.482	0.693	0.808

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors reported in parentheses. Columns 2 and 3 shows the summary statistics for the control group in the baseline. Column 3 shows the coefficient from regressing the baseline variable on a treatment dummy (taking value 1 if the respondent was in any treatment group). Columns 5 and 6 are the coefficients from regressing the baseline variable on two treatment dummies (taking the value 1 if the respondent was in a Standard PES treatment group, and taking value 1 if the respondent was in Upfront payment PES treatment group, respectively). Column 7 shows the coefficient from regressing the baseline variable on a dummy taking value 1 if the respondent was in the Upfront payment group. Regressions in Columns 4,5, and 6 use the control group as the comparison group. Regressions in Column 7 uses the standard PES group as the comparison group. All regressions cluster standard errors at the village level and include strata fixed effects. All income variables relate to income derived in the past 12 months and are measured in ₹1000. All index variables in Panel C are binary. There are 1,668 observations in the baseline; 486 observations for the control group and 1,182 observations for the treatment groups.

Table 2: Program Outcomes

	Farmer Found (1)	Farmer Eligible (2)	Contract Take-Up (3)
Standard PES	0.885 (0.014) <sup>***</sup>	0.844 (0.019) <sup>***</sup>	0.726 (0.023) <sup>***</sup>
Upfront PES	0.879 (0.011) <sup>***</sup>	0.833 (0.014) <sup>***</sup>	0.718 (0.022) <sup>***</sup>
<i>p</i> -val: Standard PES = Upfront PES	0.720	0.627	0.798
Control mean	0.000	0.000	0.000
Standard PES mean	0.887	0.852	0.741
Upfront PES mean	0.880	0.837	0.728
N	1668	1668	1668

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects included. Farmer Found is a dummy variable taking the value 1 if the respondent was available during the intervention. Farmer Eligible is a dummy variable taking the value 1 if the respondent was available during the intervention and had a bank account. Contract Take-Up is a dummy variable taking the value 1 if the respondent signed a contract to participate in the PES program.

Table 3: Contract Compliance and Not Burning

	Compiled with Contract (1)	Not Burned (Balanced Accuracy) (2)	Not Burned (Maximum Accuracy) (3)
Standard PES	0.085 (0.015) <sup>***</sup>	0.008 (0.042)	0.020 (0.030)
Upfront PES	0.183 (0.020) <sup>***</sup>	0.115 (0.042) <sup>***</sup>	0.077 (0.032) <sup>**</sup>
<i>p</i> -val: Standard PES = Upfront PES	0.000	0.008	0.071
Control mean	0.000	0.202	0.091
Standard PES mean	0.084	0.198	0.098
Upfront PES mean	0.185	0.313	0.161
N	1668	1664	1664

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects included. Complied with Contract is a dummy variable taking the value 1 if the respondent called to request monitoring of his plots, and monitoring led to the conclusion that the respondent complied with the contract i.e. did not burn his paddy residue. Not Burned takes value 1 if the farmer did not burn any of his plots, and 0 otherwise. Column 2 classifies burning to balance type I and type II errors; column 3 classifies burning to maximize overall model accuracy.

Table 4: Crop Residue Management Methods

	Baler (1)	Seeder (2)
Standard PES	-0.010 (0.037)	-0.020 (0.023)
Upfront PES	0.096 (0.039)**	0.013 (0.026)
<i>p</i> -val: Standard PES = Upfront PES	0.014	0.157
Control mean	0.199	0.102
Standard PES mean	0.171	0.087
Upfront PES mean	0.295	0.112
N	1387	1387
<i>Lee Bounds</i>		
Standard PES		
Lower bound	-0.025 (0.027)	-0.028 (0.021)
Upper bound	0.036 (0.025)	0.047 (0.017)***
Upfront PES		
Lower bound	0.088 (0.030)***	0.006 (0.022)
Upper bound	0.145 (0.028)***	0.068 (0.019)***

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Baler is a dummy variable taking value 1 if the farmer reported in the endline that he used a baler. Seeder is a dummy variable taking value 1 if the farmer reported in the endline that he used a happy seeder or a super happy seeder. The second panel shows the Lee bounds for the treatment effects by treatment group. For details on the Lee bounds, see footnote 31.

Table 5: Treatment Effects by Liquidity and Distrust

<b>Panel A: Liquidity Constraints and Distrust</b>						
<i>Outcome variable:</i>	Complied with contract		Burned (Balanced Accuracy)		Burned (Maximum Accuracy)	
<i>Type of constraint:</i>	Distrust (1)	Liquidity (2)	Distrust (3)	Liquidity (4)	Distrust (5)	Liquidity (6)
Upfront PES	0.114 (0.030)***	0.088 (0.029)***	0.031 (0.032)	0.030 (0.033)	0.054 (0.029)*	0.051 (0.029)*
Highly constrained	0.030 (0.024)	0.010 (0.022)	0.021 (0.029)	0.007 (0.035)	0.003 (0.025)	0.014 (0.030)
Upfront PES × Highly constrained	-0.032 (0.036)	0.018 (0.038)	-0.037 (0.039)	-0.032 (0.048)	-0.025 (0.039)	-0.022 (0.042)
Standard PES mean	0.083	0.084	0.167	0.167	0.104	0.105
Upfront PES mean	0.185	0.185	0.174	0.174	0.143	0.142
N	1172	1182	1168	1178	1168	1178

**Panel B: Trust in Payment and Importance of Cash Shortage**

<i>Outcome variable:</i>	Trusted Payment (1)	Cash Shortage Not Important (2)
Upfront PES	0.068** (0.028)	0.038 (0.043)
Standard PES mean	0.854	0.441
N	580	584

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. **Panel A:** Type of constraint is the heterogeneity variable which is indicated in the second row of the table: Liquidity is an index indicating liquidity constraints, including constrained access to cash and loans. Distrust is an index indicating the farmer's distrust in categories of people and organizations. All indices are binary and take value 1 if the farmer's constraints are larger than or equal to the median. The Outcome variable is indicated in the top row: Complied with Contract is a dummy variable taking the value 1 if the monitoring led to the conclusion that the respondent complied with the contract i.e. did not burn his paddy residue. The comparison group is the Standard PES group. **Panel B:** Trusted payment takes value 1 if the respondent trusted that the payment by JPAL will be made if they did not burn their paddy residue, and 0 otherwise. Cash shortage not important takes the value 1 if the respondent declared that cash shortage was not an important factor when deciding which crop residue management method to use, and 0 otherwise. These outcome variables are from the endline survey. The control group is excluded from the sample. The comparison group is the Standard PES treatment group. Only those who signed a contract i.e. took up the treatment are included in the sample.

Table 6: Cost Effectiveness

	Amount Paid per Acre (1)	Balanced Accuracy		Maximum Accuracy	
		Not Burned (2)	Cost per Unburned Acre (3)	Not Burned (4)	Cost per Unburned Acre (5)
Standard PES	105.6 (21.7) <sup>***</sup>	0.008 (0.042)	13440.5 (71152.0)	0.020 (0.030)	5156.5 (7156.0)
Upfront PES	310.5 (15.4) <sup>***</sup>	0.115 (0.042) <sup>***</sup>	2695.0 (948.7) <sup>***</sup>	0.077 (0.032) <sup>**</sup>	4051.3 (1595.0) <sup>**</sup>
<i>p</i> -val: Standard PES = Upfront PES	0.000	0.008	0.879	0.071	0.864
N	1667	1664		1664	

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Amount Paid per Acre (column 1) is the per acre payment in ₹ that the farmer received. This includes the amount paid upfront for those in the Upfront PES treatment, plus the amount paid conditional on compliance for those in the Upfront and Standard PES treatment. Not Burned takes the value 1 if the farmer did not burn any of their plots, and 0 otherwise, and matches the estimates in Table 3. Cost per Unburned Acre is the Amount Paid per Acre divided by the Not Burned (column 2 or column 4). Standard errors in columns 3 and 5 are calculated using the Delta method.

# Appendices

## Appendix A: Tables and Figures

Table A.1: Accuracy Statistics, Holdout Sample

<i>Accuracy model:</i>	Not Burned	
	Balanced Accuracy (1)	Maximum Accuracy (2)
Mean accuracy	0.78	0.82
False burn	0.08	0.13
False no burn	0.14	0.05
True burn	0.51	0.59
True no burn	0.27	0.22
No burn accuracy	0.76	0.63
Burn accuracy	0.79	0.92

Note: Accuracy statistics for remote sensing measures of burning, using different classifications thresholds. The true/false burn/no-burn rows show counts of the number of fields in each category.  $N = 705$ .

Table A.2: Attrition from the Endline Survey

	Attrition (1)
Standard PES	0.051 (0.025)**
Upfront PES	0.044 (0.025)*
$p$ -val: Standard PES = Upfront PES	0.786
Control group mean	0.130
Standard PES group mean	0.187
Upfront PES group mean	0.182
N	1668

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. The outcome variable is a dummy that takes the value 1 if the respondent attrited from the endline.

Table A.3: Remote Sensing Based Burning Outcome (Plot Level)

	Not Burned	
	Balanced Accuracy (1)	Maximum Accuracy (2)
Standard PES	0.003 (0.046)	0.022 (0.036)
Upfront PES	0.123 (0.045)***	0.101 (0.036)***
<i>p</i> -val: Standard PES = Upfront PES	0.005	0.023
Control group mean	0.296	0.150
Standard PES mean	0.284	0.154
Upfront PES mean	0.432	0.265
N	2875	2875

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Plot level regressions are weighted by the inverse of the number of plots the farmer has. Not Burned takes value 1 if the farmer did not burn any of his plots, and 0 otherwise. Column 1 classifies burning to balance type I and type II errors; column 2 classifies burning to maximize overall model accuracy.

Table A.4: Spot Checks Based Burning Outcome

	Not Burned (1)
Standard PES	0.014 (0.077)
Upfront PES	0.105 (0.073)
<i>p</i> -val: Standard PES = Upfront PES	0.233
Control mean	0.371
Standard PES mean	0.364
Upfront PES mean	0.456
N	715

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Not Burned takes value 1 if the farmer did not burn any of his plots according to the spot checks, and 0 otherwise.

Table A.5: Yield and Sowing Delay

	Paddy Yield (1)	Wheat Yield (2)	Days (3)
Standard PES	-0.026 (0.039)	-0.013 (0.015)	-0.217 (0.643)
Upfront PES	-0.066 (0.045)	0.008 (0.015)	-0.120 (0.627)
<i>p</i> -val: Standard PES = Upfront PES	0.356	0.151	0.881
Control mean	1.249	0.745	18.364
Standard PES mean	1.237	0.736	17.943
Upfront PES mean	1.194	0.756	18.380
N	1367	1378	1386
<i>Lee Bounds</i>			
Standard PES			
Lower bound	-0.103 (0.037) <sup>***</sup>	-0.035 (0.013) <sup>***</sup>	-1.032 (0.552) <sup>*</sup>
Upper bound	0.037 (0.037)	0.008 (0.015)	0.320 (0.524)
Upfront payment PES			
Lower bound	-0.113 (0.037) <sup>***</sup>	-0.013 (0.010)	-0.937 (0.532) <sup>*</sup>
Upper bound	0.005 (0.037)	0.027 (0.012) <sup>**</sup>	0.425 (0.505)

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Paddy Yield is a variable indicating the amount of paddy produced in Kharif 2019 (log of 1000 kg per acre). Wheat Yield is a variable indicating the amount of wheat produced in Rabi 2020 (log of 1000 kg per acre). Days is a variable indicating the number of days after the paddy harvest that passed before the farmer started sowing the Rabi crop. The second panel shows the Lee bounds for the treatment effects by treatment group. For details on the Lee bounds, see footnote 31.

Table A.6: Heterogeneity of Treatment Effects on Contract Compliance: CRM Equipment Constraints

<i>Outcome variable:</i>	Complied with Contract		
<i>Type of constraint:</i>	Information Constraints	Access Constraints	Negative Beliefs about Burning Alternatives
	(1)	(2)	(3)
Highly constrained	-0.063 (0.019)***	-0.004 (0.024)	-0.040 (0.020)**
Pooled PES mean	0.135	0.136	0.135
N	1182	1168	1182

Note: \*\*\*(\*\*)(\*) indicates significance at the 1%(5%)(10%) level. Standard errors in parentheses clustered at the village level. Strata fixed effects are included. Type of constraint is the heterogeneity variable which is indicated in the second row of the table: Information Constraints is an index indicating the farmer's lack of knowledge about CRM equipment. Access constraint is an index indicating the farmer's difficulties in accessing CRM equipment. Negative Beliefs about Burning Alternatives is an index indicating the strength of the farmers negative beliefs about the impact of CRM equipment on soil health and yield as compared to burning. All indices are binary and take value 1 if the farmer's constraints are larger than or equal to the median. The Outcome variable is indicated in the top row: Complied with Contract is a dummy variable taking the value 1 if the monitoring led to the conclusion that the respondent complied with the contract i.e. did not burn his paddy residue.

Figure A.1: Fires Over Time: MODIS Satellite Data

Note: Fire counts from September to December by year, based on MODIS imagery. Left panel shows the state of Punjab; right panel shows study districts. The line at 2015 indicates the introduction of the burning ban; the line at 2017 indicates the introduction of the two-year CRM subsidy.

Figure A.2: Signature of Burning in Imagery: Example

Around harvest time

Just after burning

One week after burning

Note: Imagery from Sentinel-2 showing a study field.

Figure A.3: Distribution of Random Forest Predictions by Treatment

Note: The left panel shows the distribution of the continuous remote sensing measure of not burning for the plots classified as having been burned. The right panel shows the distribution of the same measure for plots classified as not having been burned. The classification uses the balanced accuracy, and restricts to plots not included in the training data. The continuous remote sensing measure ranges from 0 to 1, where higher values mean that it is more likely that the plot has not been burned.

Figure A.4: Treatment Effects on Program Outcomes

Note: Coefficients on top of bars. \*\*\*(\*\*)(\*) indicates significant difference between coefficients at the 1%(5%)(10%) level. Contract Take-Up is a dummy variable taking the value 1 if the respondent signed a contract to participate in the PES program. Complied with Contract is a dummy variable taking the value 1 if the monitoring led to the conclusion that the respondent complied with the contract i.e. did not burn his paddy residue. Not Burned takes value 1 if the farmer did not burn any of his plots, and 0 otherwise, using the balanced accuracy which classifies burning to balance type I and type II errors. 800/acre is the Standard PES group receiving ₹800 per acre conditional on not burning. 1600/acre is the Standard PES group receiving ₹1600 per acre conditional on not burning. 800/acre with 25% upfront is the Upfront PES group receiving ₹800 per acre of which they receive 25% unconditionally upfront and 75% conditional on not burning. 800/acre with 50% upfront is the Upfront PES group receiving ₹800 per acre of which they receive 50% unconditionally upfront and 50% conditional on not burning.

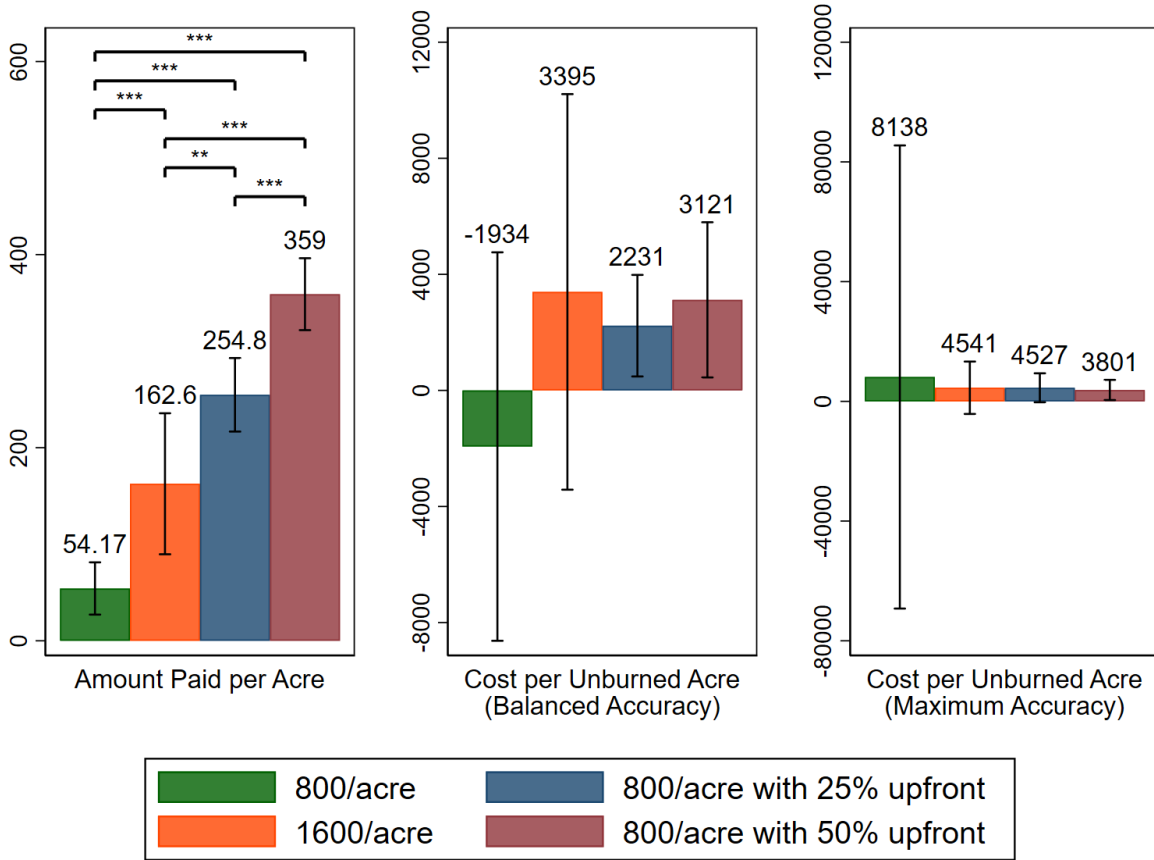

Figure A.5: Robustness of Treatment Effects on Not Burning

Note: The graphs show the control mean and treatment effects for binary remote sensing measures of not burning based on different classification thresholds. The classification thresholds are indicated on the x-axis. The binary remote sensing measures of not burning take value 1 if the farmer did not burn any of his plots, and 0 otherwise. The first graph shows the mean of the remote sensing measure of not burning in the control group. The second graph shows the treatment effects on not burning in the Standard PES treatment arm. The third graph shows the treatment effects on not burning in the Upfront PES treatment arm. The two red lines in the second and third graph indicate the thresholds used for the remote sensing measures of not burning with balanced accuracy which classifies burning to balance type I and type II errors, and with maximum accuracy which classifies burning to maximize overall model accuracy. The remote sensing measure of not burning with balanced accuracy uses a threshold of 56 and the one with maximum accuracy uses a threshold of 65.

Figure A.6: Cost Effectiveness

Note: Coefficients on top of bars. \*\*\*(\*\*)(\*) indicates significant difference between coefficients at the 1%(5%)(10%) level. Amount Paid is the payment in Rs the farmer received (it is the total amount for those who were monitored and did comply (i.e. did not burn), it is the upfront amount for any respondents in the treatment groups with upfront component who participated but did not call for monitoring/burned, and it is 0 for respondents in treatment groups without upfront component who did not call for monitoring/burned, for respondents in any treatment groups who did not participate, as well as for respondents in the control group). Acreage Averted is the number of acres not being burned according to the remote sensing data. Cost per Acre is column 1 divided by column 2. 800/acre is the Standard PES group receiving ₹800 per acre conditional on not burning. 1600/acre is the Standard PES group receiving ₹1600 per acre conditional on not burning. 800/acre with 25% upfront is the Upfront PES group receiving ₹800 per acre of which they receive 25% unconditionally upfront and 75% conditional on not burning. 800/acre with 50% upfront is the Upfront PES group receiving ₹800 per acre of which they receive 50% unconditionally upfront and 50% conditional on not burning.

## Appendix B: Survey questions used in constructing indices for heterogeneous treatment effects

This section details the (pre-specified) survey questions used in constructing the indices for heterogeneous treatment effects.

### Financial constraints

1. If you needed to spend ₹5000 for agricultural equipment, would you have savings to draw on?
2. If you needed to spend ₹10,000 for agricultural equipment, would you have savings to draw on?
3. If you needed to spend ₹5000 for agricultural equipment, how easy would it be for you to get a loan for that amount?
4. If you needed to spend ₹10,000 for agricultural equipment, how easy would it be for you to get a loan for that amount?

These (standardized) variables are used to create an index, which is used to create a binary variable split at the median to denote high financial constraints.

### Distrust

1. Generally speaking, would you say that most people can be trusted or that you need to be very careful in dealing with people?
2. I'd like to ask you how much you trust people from various groups. Could you tell me for each whether you trust people from this group completely, somewhat, not very much or not at all?
  - People in your neighborhood?
  - Strangers?

3. Even if you have had very little or no contact with these following institutions, please base your answer on your general impression of these institutions.

- The Punjab Government?
- The village Panchayat?
- The cooperative society?
- Non-governmental organizations (NGOs)?
- Financial Institutions like Banks/Insurance Companies?

### **CRM access barriers indices**

We construct three indices to measure different aspects of CRM equipment access barriers. The first measures information constraints, the second access barriers, and the third beliefs about how CRM equipment impacts agriculture relative to burning. All questions except the first are asked about the CRM equipment farmers reported being familiar with.

#### *Information Constraints*

1. Do you know about any crop residue management techniques to manage paddy stubble?
2. Where can you rent it (CRM equipment) from?

#### *Access Barriers*

1. Do you own [CRM equipment] as an individual or member of a CHC or Coop?
2. Is using [CRM equipment] more expensive or less expensive than burning paddy stubble?
3. In days, how long would it take you to access crop residue management equipment for managing paddy stubble at harvest time this year?
4. Including all costs, how much would the equipment cost per acre (in Rs.)?
5. How many days would it take to manage paddy stubble using this equipment?

*Negative Beliefs About CRM Equipment*

- Is using [CRM equipment] better for long-term soil health or worse for soil health than burning paddy stubble?
- Does using [CRM equipment] help yield of rabi season or hurt yield of rabi season compared to burning paddy stubble?

## **Appendix C: Intervention script**

### **Program description**

Our organization is working on agricultural and environmental issues and we want to help farmers manage paddy stubble after the paddy harvest this season. I am here to share details of a program that we are introducing to some farmers in this village during the paddy crop season in the month of October and November 2019.

To encourage farmers to manage paddy stubble in an environmentally-friendly manner, we will offer you an agreement that will pay you if you do not burn your paddy field(s) this season. We will compensate you at a rate of [treatment rate] per acre (up to a max. of [treat rate x 100]). You may use any alternate methods of managing the residue. Other than burning the stubble, we do not place any condition on what this method should be.

This monetary compensation will only be given to you if a monitor, during the months of October and November, assesses that that your paddy field has not been burned. If you are interested in participating, I will explain the terms and conditions of the agreement to you that will help you decide whether you want to enroll in the programme or not. If you are uncertain about signing the agreement because you are unsure whether you would be fulfilling the conditions of the contract, let me remind you that there is no harm in participating in the programme. If you burn, you will not be penalized in any way by us. If you do not burn, you will be given the reward. By signing you are only giving yourself a chance to win money.

If you would like someone in the house to help you make a decision and listen to the details of the programme, please feel free to invite them now. Please remember that whoever signs the agreement must have a bank account to enable payments at a later date.

### **Information handout**

This document provides details on some of the items in the agreement and is to help the enrollee farmer with complying with the terms and conditions of the agreement.

#### **Monitoring visits**

1. The enrollee farmer is expected to initiate monitoring for all plots, with a maximum of two requests to J-PAL. All plots must be covered through these two requests.
2. Each request will result in up to two visits by J-PAL monitors. The second visit will only be performed if J-PAL determines that it is necessary to assess burning.
3. In addition to the requested and scheduled visits, J-PAL can also make unannounced visits to the plots for checks.

**When to call for monitoring:** The enrollee farmer should call once all the pre-sowing work related to stubble has been completed on the plots covered under the request. This means all activities related to stubble like removing or processing of stubble must have been completed and no further managing of stubble is required before sowing. In general, requests should be made at least four days before sowing. The request can occur if any of the following applies:

1. After the straw and stubble have been completely removed from the plot but no later than 4 days before sowing.
2. After the straw has been rolled into bales/bundles but no later than four days before sowing.
3. After the straw/stubble has been mixed or blended into the soil but no later than four days before sowing.
4. If using the Happy seeder or mulcher: once sowing preparation is complete but no later than four days before sowing. In these cases, a second monitoring visit will be made post sowing.

Remember, up to two requests can be initiated. If some plots are ready, call to schedule the first monitoring, keeping in mind that any plots not covered under the first request have to be monitored as part of the second request. If all plots are ready for monitoring, they can be inspected in a single visit.

Phone numbers for calling: xxx, xxx, xxx

What counts as burning? The agreement requires that farmers do not burn any of their plots. This will be broken if any of the following (or any other form of burning) are detected by the monitor. The farmer will not be eligible for payment if any of the following is detected during monitoring.

- Burning of the upper layer of loose straw left behind by the harvester.
- Burning of the standing stubble.
- Burning of straw collected in one part of the plot.
- Burning as mentioned above on any of the plots.

#### Important

1. J-PAL SA is not related to any government in any manner. The failure of the enrollee farmer to meet any term or condition in the agreement will not attract any penalty or fine, and no legal action will be taken. This is clearly stated in the agreement. We are only trying to find if this a good way to help the farmers with resolving the residue issue. We cannot impose any fines or penalties since we are not related to government.
2. The only consequence of not fulfilling any of the term or condition in the agreement will be that farmer will become ineligible for payment of amount as mentioned in the agreement.
3. In case the farmer does not request monitoring as specified above, J-PAL will not be liable to pay any amount as mentioned in the agreement. Decision on payment to be made will only be taken once all the plots have been fully monitored.
4. If after the first monitoring visit and after analyzing the observations recorded, the J-PAL SA team ascertains that burning happened in even one of the plots, no further monitoring visit will be conducted. In this case, the farmer will be ineligible to receive the payment.
5. At the time of the monitoring visit, we may also request you for bank account details. The bank account transfer is the fastest and easiest way to transfer the amount. After

the monitoring has been completed for all the plots and it is assessed that burning has not happened on any plots, the payment will be made directly into the account.

6. The enrollee farmer should keep the agreement and information handout safe for use later. The ID and phone numbers given on them are to be used for calling.

## A.1 Appendix D: Sample Contract

$\{\text{village\_id}\}$

$\{\text{a\_hhid}\}$

$\{\text{resp\_id}\}$

### **Contract for Incentive Program Offering Payment for No-Burning on Paddy Plots**

This Agreement is executed on \_\_\_\_\_ [Insert date]

by and between  $\{\text{resp\_name}\}$ ,

residing at

\_\_\_\_\_ [Insert Enrollee Address]

### **AND**

Abdul Latif Jameel Poverty Action Lab South Asia at the Institute for Financial Management and Research, which is registered under Society Registration Act 1860 (hereinafter referred to as “J-PAL SA”), located at Buhari Towers, 2<sup>nd</sup> Floor, 4, Moors Road, Chennai 600006

### **Background**

J-PAL SA proposes to partner with [ $\{\text{resp\_name}\}$ ] (hereinafter referred to as “Enrollee”) with the following summary of responsibilities.

Based on the field measurement completed in a previous visit, (s)he cultivates **#ACRE** \_\_\_\_\_ acres of paddy currently.

### **Summary of responsibilities**

## ***J-PAL SA***

1. Visit Enrollee's paddy plots, which were mapped during the survey visit to the Enrollee that was already conducted, to assess whether burning occurred. This monitoring visit will take place once Enrollee informs J-PAL SA by phone, as described below. J-PAL will visit the plots to assess whether they have been burned within **3** days of being called by the Enrollee. Monitoring will be available only beginning on 15 October 2019 or today (whichever date is later). Enrollees that call to be monitored before this date cannot be monitored by J-PAL South Asia and therefore are not eligible for payment.
2. The J-PAL SA team will determine if the field has been burned based on the observations made by the monitor during their visit. The process of inspection is summarized below:
  - a) The J-PAL SA monitor will visit all the paddy plots as measured during a previous visit.
  - b) The monitor will physically inspect each plot for visual cues and record the observations. Based on the recorded observations during the visit, the J-PAL SA team will determine whether the field was burned or not.
3. If the paddy plots do not appear to be burned, as assessed by the J-PAL SA team, then J-PAL SA will provide Enrollee with an amount such that the total payment amount for not burning is Rs **800** per acre of enrolled land. The maximum overall payment is Rs **8000**. The payment amount for the Enrollee is Rs  $\{pes\_amount\}$ .

## ***Enrollee***

1. Enrollee confirms, by signing this agreement, that the paddy plots mapped during the survey visit represent all of his/her paddy plots. All paddy plots cultivated in the 2019 Kharif season must be enrolled.
2. After harvesting paddy and managing and processing stubble, and at least **4 days** before sowing wheat or any other rabi crop, Enrollee is required to call J-PAL SA at the numbers provided on the information handout between the hours of 9:00 am and 5:00 pm, on any date between **15 October** and **30 November 2019** to indicate that the fields are ready to be monitored. We will not be able to monitor before the above mentioned date and farmers requesting for monitoring to be conducted before the 15<sup>th</sup> October will not be eligible.
3. The Enrollee may request up to two monitoring visits to cover all paddy plots, for example, for some plots that are ready for monitoring early and others that are ready late. Each plot will be monitored up to two times.
4. The Enrollee will also allow additional, unscheduled monitoring to occur at any point in time.

5. If it is assessed by the J-PAL SA team that the field is not burnt, the Enrollee will receive a payment amount as indicated above. For the enrollee to be eligible for payment, no burning should have taken place on any of the plots.
6. The assessment of whether a field is burnt or not is not dependent on whether the field was burnt deliberately or accidentally, or by the Enrollee or someone else.

**Payment and contract**

1. J-PAL SA shall not be obligated to pay the Enrollee any amount in excess of what is mentioned above.
2. By signing this agreement, the Enrollee acknowledges that J-PAL SA reserves the right to rescind the payment of the aforementioned amount if the Enrollee fails to fulfil any of the responsibilities designated to him/her under “Summary of Responsibilities” and/or breach of the terms of this agreement in any manner or extent.
3. There will be no legal implications for the Enrollee for the breach of the agreement. J-PAL SA will not take any legal action against the Enrollee if one or more responsibilities remain unfulfilled under the agreement.
